# Index calculus

solve  $g^x \equiv h \pmod{p}$   
 e.g.  $3^x \equiv 37 \pmod{1217}$

- factor base  $p_i = \{2,3,5,7,11,13,17,19\}$ ,  $\#p_i = 8$
- Find 8 values of  $k$  where  $3^k$  splits over  $p_i$ , i.e.,  $3^k \equiv \pm \prod p_i \pmod{p}$

(mod 1217)		(mod 1216)		(mod 1216)
$3^1 \equiv 3$		$1 \equiv L(3)$		$L(2) \equiv 216$
$3^{24} \equiv -2^2 \cdot 7 \cdot 13$		$24 \equiv 608 + 2 \cdot L(2) + L(7) + L(13)$		$L(3) \equiv 1$
$3^{25} \equiv 5^3$		$25 \equiv 3 \cdot L(5)$		$L(5) \equiv 819$
$3^{30} \equiv -2 \cdot 5^2$		$30 \equiv 608 + L(2) + 2 \cdot L(5)$		$L(7) \equiv 113$
$3^{34} \equiv -3 \cdot 7 \cdot 19$		$34 \equiv 608 + L(3) + L(7) + L(19)$		$L(11) \equiv 1059$
$3^{54} \equiv -5 \cdot 11$		$54 \equiv 608 + L(5) + L(11)$		$L(13) \equiv 87$
$3^{71} \equiv -17$		$71 \equiv 608 + L(17)$		$L(17) \equiv 679$
$3^{87} \equiv 13$		$87 \equiv L(13)$		$L(19) \equiv 528$

# Index calculus

$$\begin{array}{l} \text{solve} \quad g^x \equiv h \pmod{p} \\ \text{e.g.} \quad 3^x \equiv 37 \pmod{1217} \end{array}$$

$$\begin{array}{l} L(2) \equiv 216 \\ L(3) \equiv 1 \\ L(5) \equiv 819 \\ L(7) \equiv 113 \\ L(11) \equiv 1059 \\ L(13) \equiv 87 \\ L(17) \equiv 679 \\ L(19) \equiv 528 \end{array}$$

Now search for  $j$  such that  $g^j \cdot h = 3^j \cdot 37$  factors over  $p_i$

$$3^{16} \cdot 37 \equiv 2^3 \cdot 7 \cdot 11 \pmod{1217}$$

$$\begin{aligned} L(37) &\equiv 3 \cdot L(2) + L(7) + L(11) - 16 \pmod{1216} \\ &\equiv 3 \cdot 216 + 113 + 1059 - 1 \\ &\equiv 588 \end{aligned}$$

$$\text{Subexponential complexity } L_p\left[1/3, (64/9)^{1/3}\right] = e^{\left(\left(64/9\right)^{1/3} + o(1)\right)(\ln(p))^{1/3} \cdot (\ln \ln(p))^{2/3}}$$

# Diffie-Hellman key exchange (cont.)

- Individual secret keys secure under Discrete Log Problem (DLP):  $g, g^x \mapsto x$
- Shared secret secure under Diffie-Hellman Problem (DHP):  $g, g^a, g^b \mapsto g^{ab}$
- Fundamental operation in DH is group exponentiation:  $g, x \mapsto g^x$   
... done via “square-and-multiply”, e.g.,  $(x)_2 = (1,0,1,1,0,0,0,1 \dots)$
- We are working “**mod**  $q$ ”, but only with one operation: multiplication
- Main reason for fields being so big: (sub-exponential) index calculus attacks!

# DH key exchange (Koblitz-Miller style)

If all we need is a group, why not use elliptic curve groups?

## Elliptic Curve Cryptosystems

By Neal Koblitz

*This paper is dedicated to Daniel Shanks on the occasion of his seventieth birthday*

**Abstract.** We discuss analogs based on elliptic curves over finite fields of public key cryptosystems which use the multiplicative group of a finite field. These elliptic curve cryptosystems may be more secure, because the analog of the discrete logarithm problem on elliptic curves is likely to be harder than the classical discrete logarithm problem, especially over  $GF(2^n)$ . We discuss the question of primitive points on an elliptic curve modulo  $p$ , and give a theorem on nonsmoothness of the order of the cyclic subgroup generated by a global point.

**1. Introduction.** The earliest public key cryptosystems using number theory were based on the structure either of the multiplicative group  $(\mathbb{Z}/N\mathbb{Z})^*$  or the multiplicative group of a finite field  $GF(q)$ ,  $q = p^n$ . The subsequent construction of analogous systems based on other finite Abelian groups, together with H. W. Lenstra's success in using elliptic curves for integer factorization, make it natural to study the possibility of public key cryptography based on the structure of the group of points of an elliptic curve over a large finite field. We first briefly recall the facts we need about such elliptic curves (for more details, see [4] or [5]). We then describe elliptic curve analogs of the Massey-Omura and ElGamal systems. We give some concrete examples, discuss the question of primitive points, and conclude with a theorem concerning the probability that the order of a cyclic subgroup is nonsmooth.

I would like to thank A. Odlyzko for valuable discussions and correspondence, and for sending me a preprint by V. S. Miller, who independently arrived at some similar ideas about elliptic curves and cryptography.

**2. Elliptic Curves.** An elliptic curve  $E_K$  defined over a field  $K$  of characteristic  $\neq 2$  or  $3$  is the set of solutions  $(x, y) \in K^2$  to the equation

$$(1) \quad y^2 = x^3 + ax + b, \quad a, b \in K$$

(where the cubic on the right has no multiple roots). More precisely, it is the set of such solutions together with a "point at infinity" (with homogeneous coordinates  $(0, 1, 0)$ ; if  $K$  is the real numbers, this corresponds to the vertical direction which the tangent line to  $E_K$  approaches as  $x \rightarrow \infty$ ). One can start out with a more complicated general formula for  $E_K$  which can easily be reduced to (1) by a linear change of variables whenever  $\text{char} K \neq 2, 3$ . If  $\text{char} K = 2$ —an important case in

## Use of Elliptic Curves in Cryptography

Victor S. Miller

Exploratory Computer Science, IBM Research, P.O. Box 218, Yorktown Heights, NY 10598

### ABSTRACT

We discuss the use of elliptic curves in cryptography. In particular, we propose an analogue of the Diffie-Hellman key exchange protocol which appears to be immune from attacks of the style of Western, Miller, and Adleman. With the current bounds for infeasible attack, it appears to be about 20% faster than the Diffie-Hellman scheme over  $GF(p)$ . As computational power grows, this disparity should get rapidly bigger.

H.C. Williams (Ed.): *Advances in Cryptology - CRYPTO '85*, LNCS 218, pp. 417-426, 1986.

group  $(G, +)$

can do  $+$   $-$

ring  $(R, +, \times)$

can do  $+$   $-$   $\times$

field  $(F, +, \times)$

can do  $+$   $-$   $\times$   $\div$

If you've never seen an elliptic curve before....

Remember: an elliptic curve is a group defined over a field

elliptic curve group  $(E, \oplus)$

can do  $\oplus \ominus$

underlying field  $(K, +, \times)$

can do  $+ - \times \div$

operations in underlying field are used and combined to  
compute the elliptic curve operation  $\oplus$

# Boring curves

$$f(x, y) = 0 \quad \text{or} \quad f(X, Y, Z) = 0$$

Degree 1 (lines)

$$ax + by = c$$

$$ab \neq 0$$

Degree 2 (conic sections)

$$ax^2 + bxy + cy^2 + dx + ey + f = 0$$

$$abc \neq 0$$

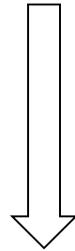

e.g., ellipses, hyperbolas, parabolas

- “Genus” measures geometric complexity, and both are genus 0
- We know how to describe all solutions to these, e.g., over (exts of)  $\mathbb{Q}$
- Not cryptographically interesting

# Elliptic curves

- Degree 3 is where all the fun begins...

$$ax^3 + bx^2y + cxy^2 + dy^3 + ex^2 + fxy + gy^2 + hx + iy + j = 0$$

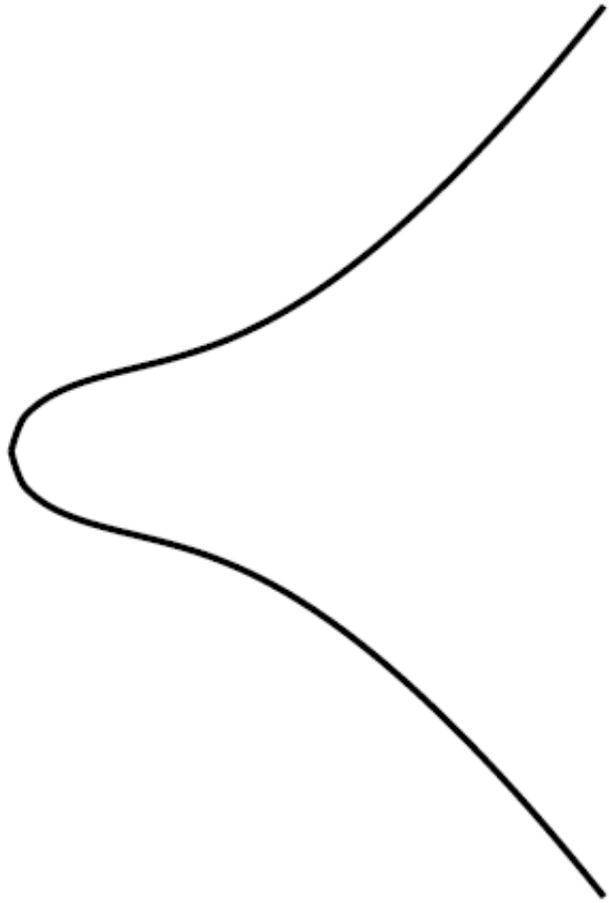

$ch(K) \neq 2,3$

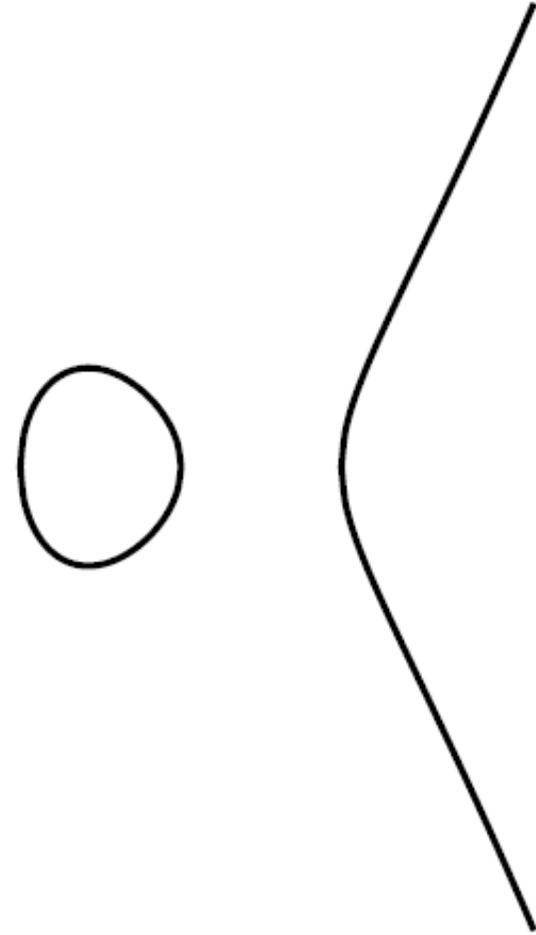

$E/K: y^2 = x^3 + ax + b$  ←  $E$  specified by  $K, a, b$

- Elliptic curves  $\leftrightarrow$  genus 1 curves
- Set is  $\approx$  points  $(x, y) \in K \times K$  satisfying above equation
- Geometrically/arithmetically/cryptographically interesting
- Fermat's last theorem/BSD conjecture/ ...

# Elliptic curves, pictorially

$$E/\mathbb{R} : y^2 = x^3 + x + 1$$

$$E/\mathbb{R} : y^2 = x^3 - x$$

# Elliptic curves are groups

- So  $E$  is a set, but to be a group we need an *operation*
- The operation is between points  $(x_P, y_P) \oplus (x_Q, y_Q) = (x_R, y_R)$
- Remember: a group  $(E, \oplus)$  defined over a field  $(K, +, \times)$
- $K$  will be fields we're used to, e.g.,  $\mathbb{Q}, \mathbb{C}, \mathbb{R}, \mathbb{F}_p$
- Remember: the (boring) operations  $+, -, \times, \div$  in  $K$  are used to compute the (exotic) operation  $\oplus$  on  $E$

# Elliptic curve group law is easy

**Fun fact:** homomorphism between Jacobian of elliptic curve and elliptic curve itself.

**Upshot:** you don't have to know what a Jacobian is to understand/do elliptic curve cryptography

# The elliptic curve group law $\oplus$

$$\text{We need } (x_P, y_P) \oplus (x_Q, y_Q) = (x_R, y_R)$$

**Question:** Given two points lying on a cubic curve, how can we use their coordinates to give a third point lying on the curve?

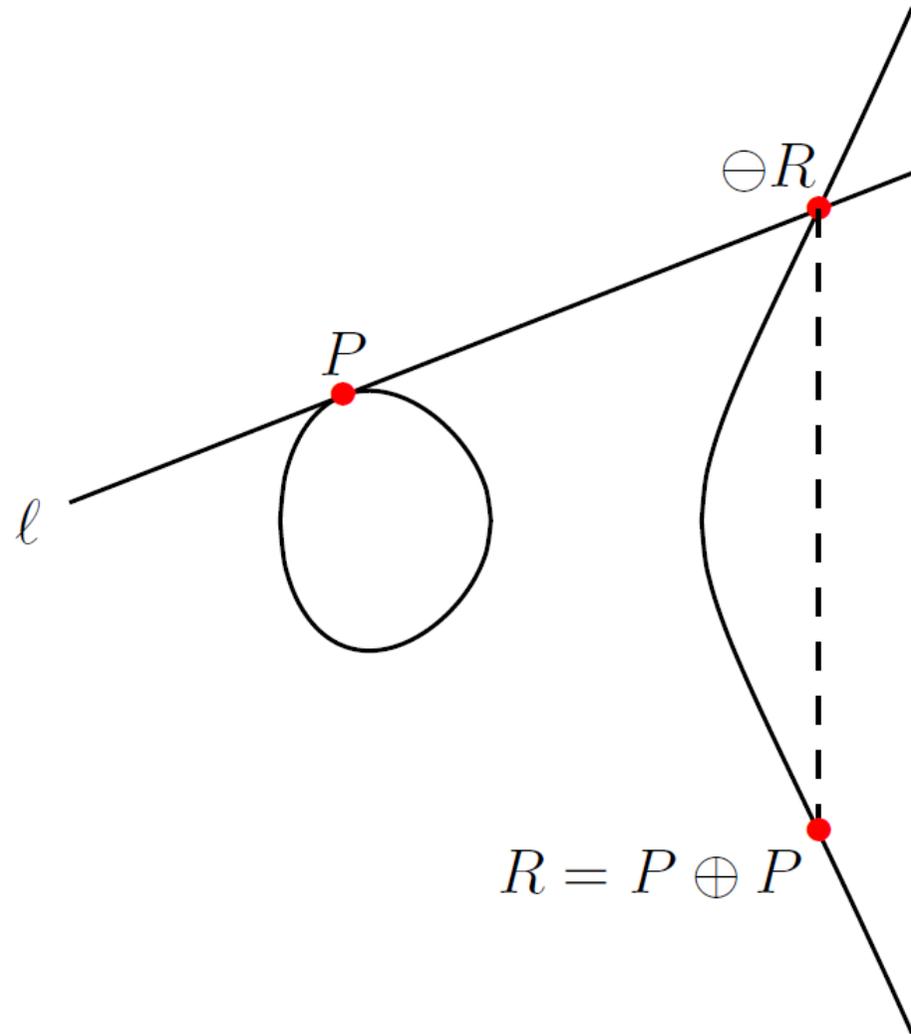

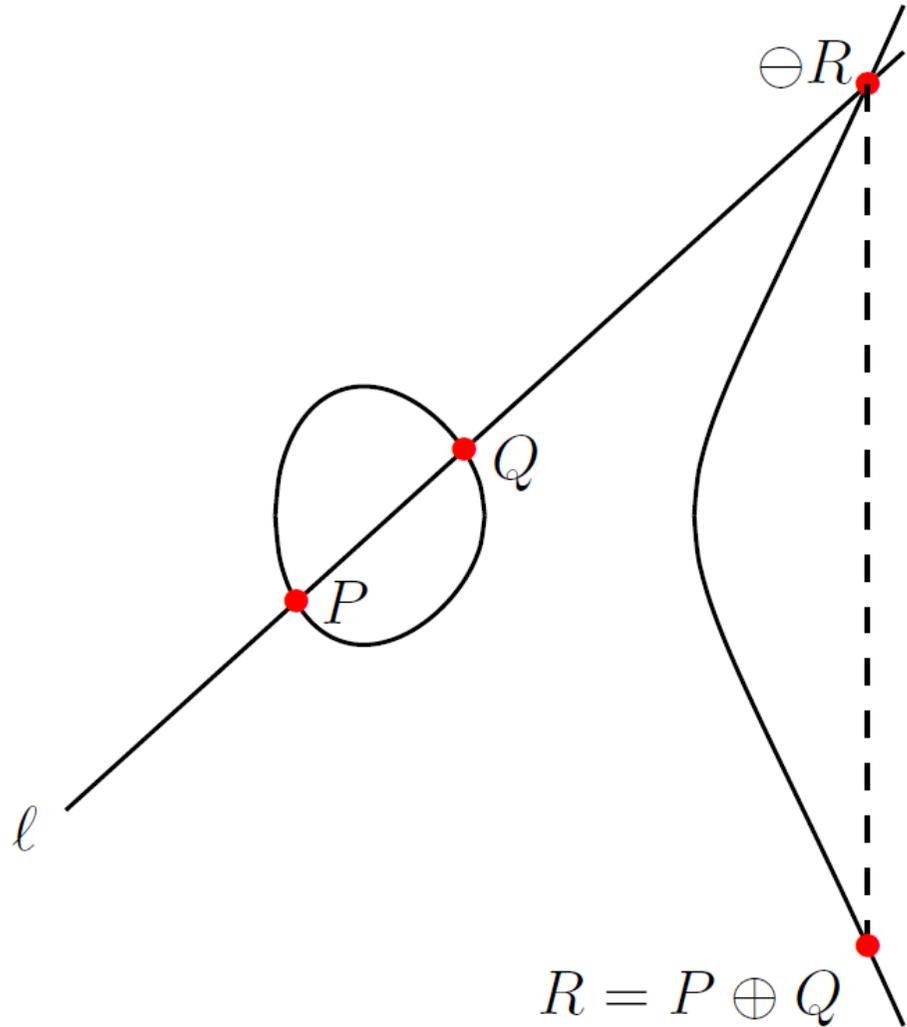

# The elliptic curve group law $\oplus$

$$\text{We need } (x_P, y_P) \oplus (x_Q, y_Q) = (x_R, y_R)$$

**Question:** Given two points lying on a cubic curve, how can we use their coordinates to give a third point lying on the curve?

**Answer:** A line that intersects a cubic twice must intersect it again, so we draw a line through the points  $(x_P, y_P)$  and  $(x_Q, y_Q)$

# The elliptic curve group law $\oplus$

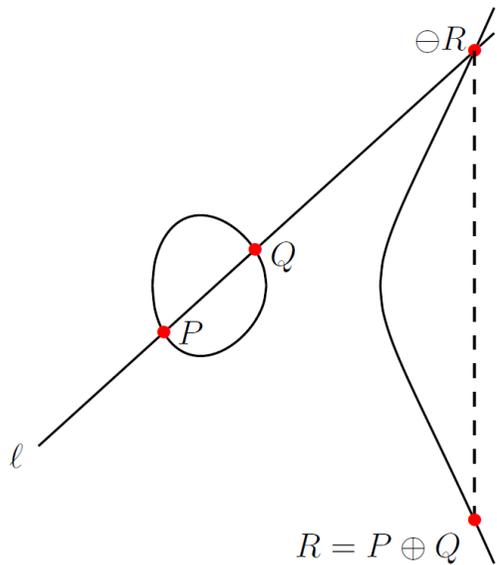

# The elliptic curve group law $\oplus$

$y = \lambda x + v$  intersected with  $y^2 = x^3 + ax + b$

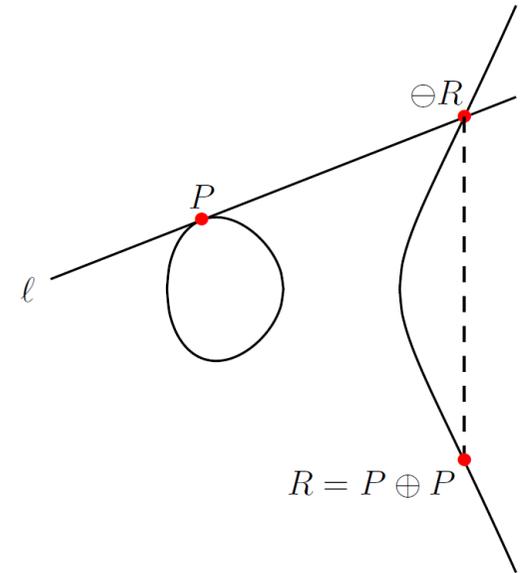

$$x^3 - (\lambda x + v)^2 + ax + b = 0$$

$$x^3 - \lambda^2 x^2 + (a - 2\lambda v)x + (b - v^2) = (x - x_P)(x - x_Q)(x - x_R)$$

$$x_R = \lambda^2 - x_1 - x_2$$

$$y_R = -(\lambda x_R + v)$$

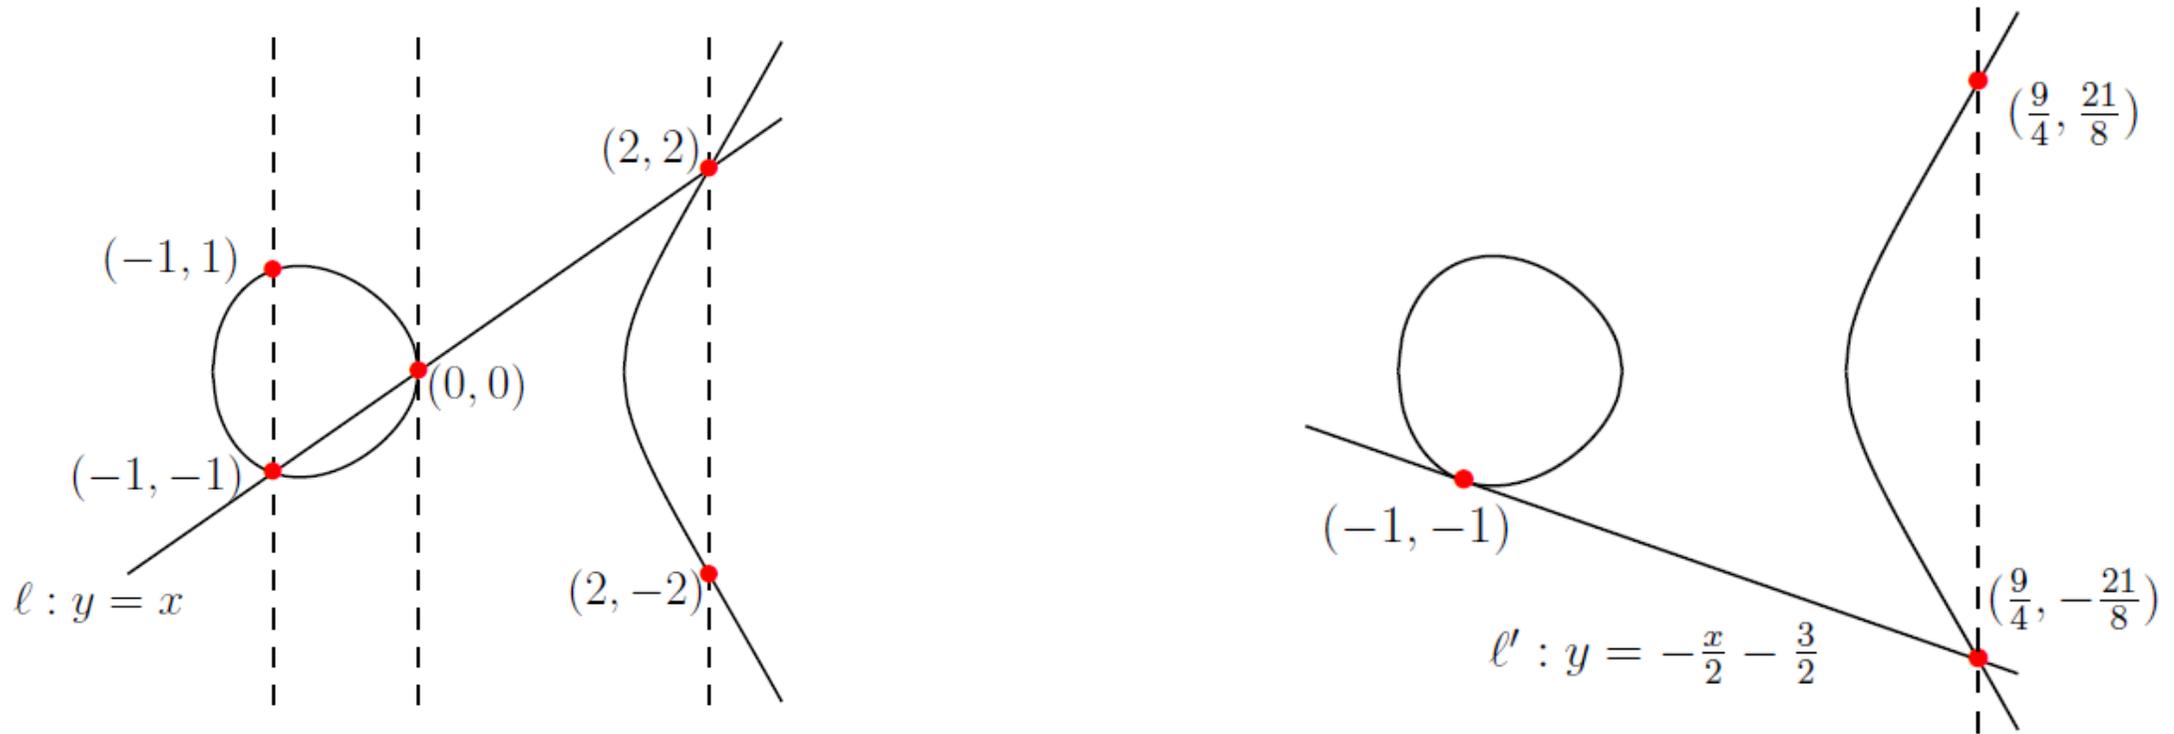

$$\lambda = \frac{dy}{dx} = \frac{3x_P^2 + a}{2y_P}$$

$$\lambda = \frac{y_Q - y_P}{x_Q - x_P}$$

# A toy example

$$E/\mathbb{R} : y^2 = x^3 - 2x$$

What about  $E/\mathbb{Q} : y^2 = x^3 - 2$  ?

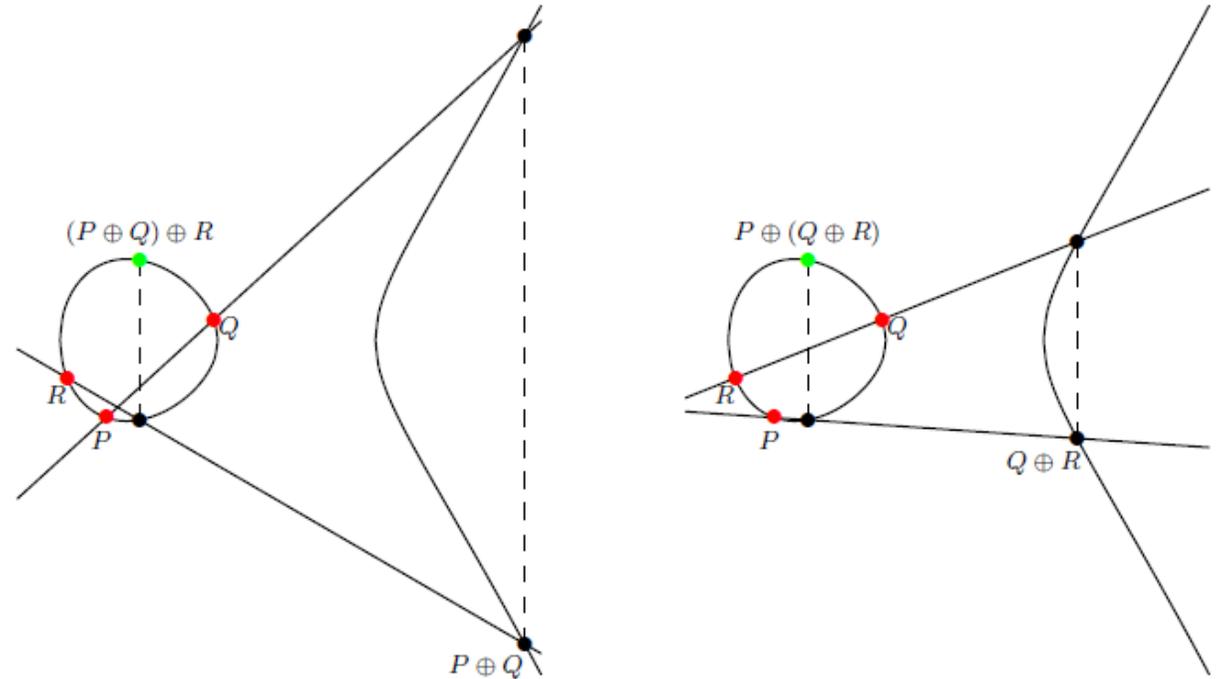

# The (abelian) group axioms

- **Closure:** the third point of intersection must be in the field

- **Identity:**  $E_{a,b}(K) = \{(x, y) : y^2 = x^3 + ax + b\} \cup \{\infty\}$

- **Inverse:**  $\ominus (x, y) = (x, -y)$

- **Associative:** proof by picture

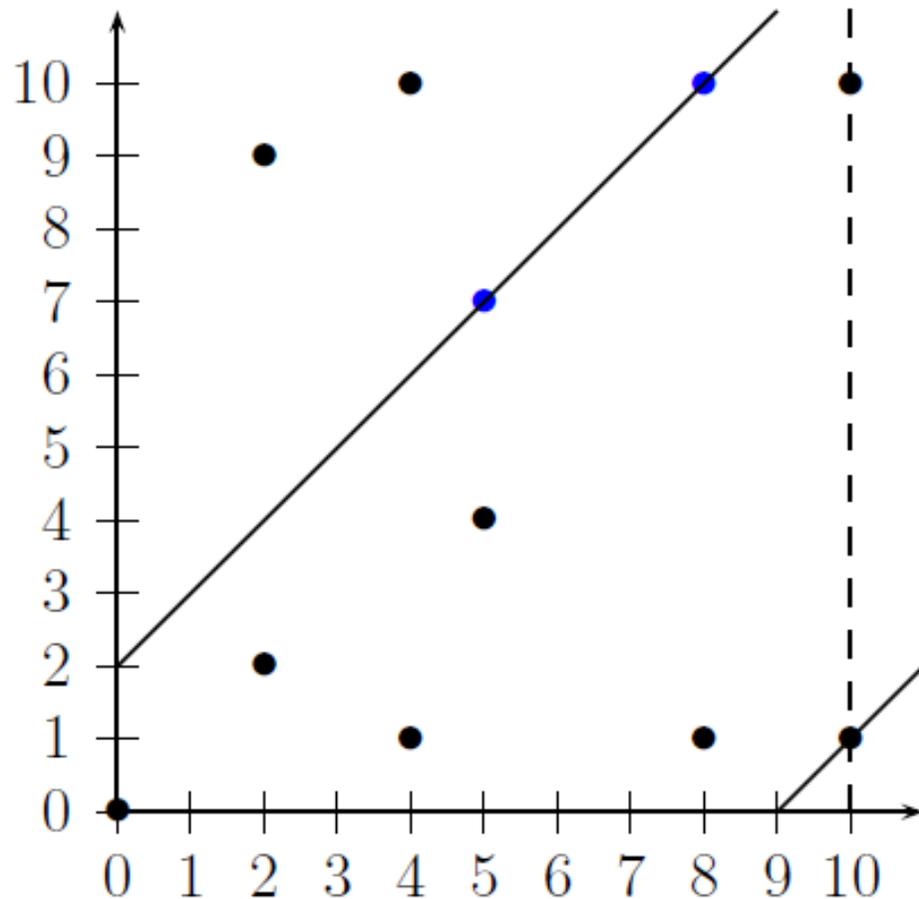

- **Commutative:** line through  $P$  and  $Q$  same as line through  $Q$  and  $P$

A toy example, cont.

$$E/\mathbb{F}_{11}: y^2 = x^3 - 2x$$

$$\#E = 12$$

$$(7,5) \oplus (8,10) = (10,1)$$

Part 1: Motivation

Part 2: Elliptic Curves

Part 3: Elliptic Curve Cryptography

Part 4: Next-generation ECC

# The fundamental ECC operation

$$P, k \mapsto [k]P$$

# Scalar multiplications via double-and-add

How to (naively) compute  $k, Q \mapsto [k]Q$  ?

$$P \leftarrow Q$$

$$k = (k_n, k_{n-1}, \dots, k_0)_2$$

for  $i$  from  $n - 1$  downto 0 do

$$P \leftarrow [2]P$$

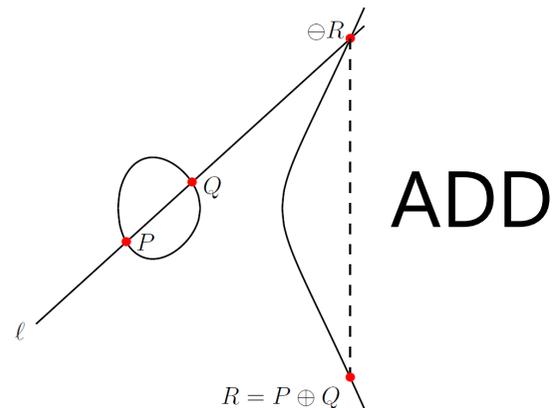

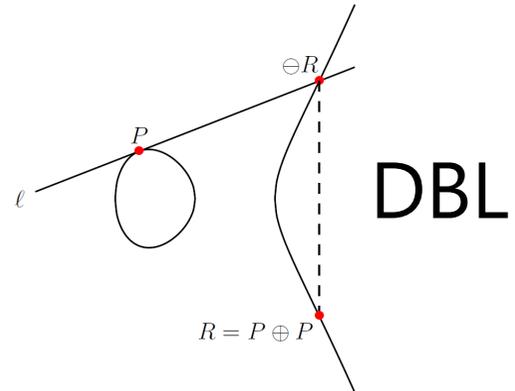

if  $k_i = 1$  then

$$P \leftarrow P \oplus Q$$

end if

end for

return  $P (= [k]Q)$

# Scalar multiplications via double-and-add

How to (naively) compute  $k, Q \mapsto [k]Q$  ?

$$P \leftarrow Q$$

$$k = (k_n, k_{n-1}, \dots, k_0)_2$$

for  $i$  from  $n - 1$  downto 0 do

$$P \leftarrow [2]P$$

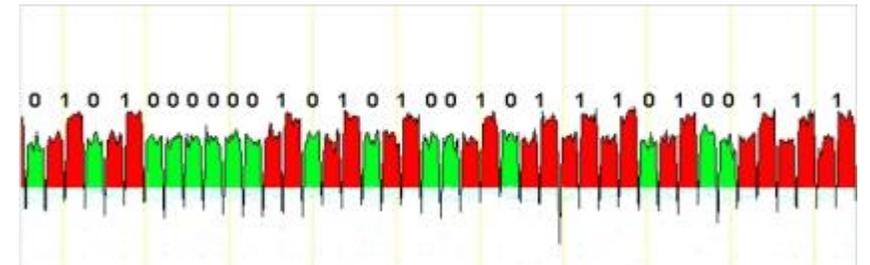

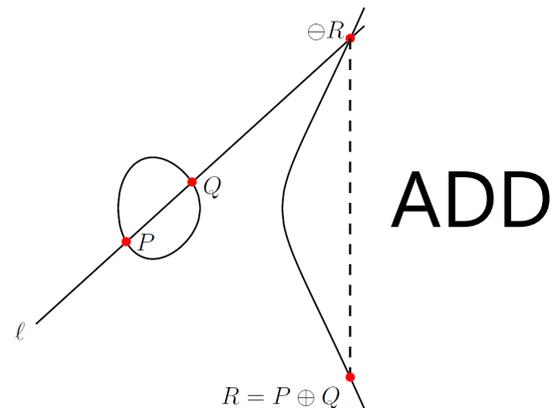

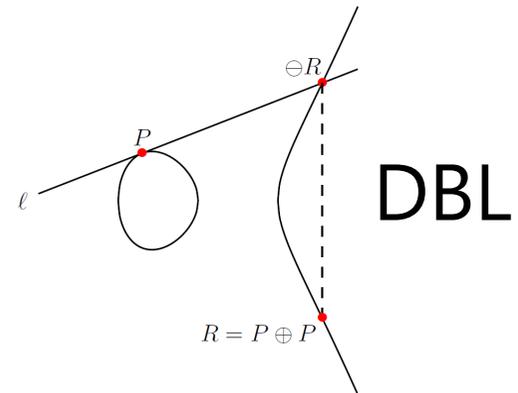

if  $k_i = 1$  then

$$P \leftarrow P \oplus Q$$

end if

end for

return  $P (= [k]Q)$

# Scalar multiplications via double-and-add

How to compute  $k, Q \mapsto [k]Q$  on  $y^2 = x^3 + ax + b$ ?

$$k = (k_n, k_{n-1}, \dots, k_0)$$

$$(x_P, y_P) \leftarrow Q$$

for  $i$  from  $n - 1$  downto 0 do

$$\lambda \leftarrow (3x_P^2 + a)/(2y_P); \quad v \leftarrow y_P - \lambda x_P;$$

$$x_P \leftarrow \lambda^2 - 2x_P; \quad y_P \leftarrow -(\lambda x_P + v);$$

if  $k_i = 1$  then

$$\lambda \leftarrow (y_P - y_Q)/(x_P - x_Q); \quad v \leftarrow y_P - \lambda x_P;$$

$$x_P \leftarrow \lambda^2 - x_P - x_Q; \quad y_P \leftarrow -(\lambda x_P + v)$$

end for

$$\text{return } (x_P, y_P) = [k](x_Q, y_Q)$$

# Projective space

- Recall we defined the group of  $K$ -rational points as

$$E_{a,b}(K) = \{(x, y): y^2 = x^3 + ax + b\} \cup \{\infty\}$$

- The *natural habitat* for elliptic curve groups is in  $\mathbb{P}^2(K)$ , not  $\mathbb{A}^2(K)$
- For (easiest) example, rather than  $(x, y) \in \mathbb{A}^2$ , take  $(X:Y:Z) \in \mathbb{P}^2$  modulo the equivalence  $(X:Y:Z) \sim (\lambda X : \lambda Y : \lambda Z)$  for  $\lambda \in K^*$
- Replace  $x$  with  $X/Z$  and  $y$  with  $Y/Z$ , so  $E_{a,b}(K)$  is the set of solutions  $(X:Y:Z) \in \mathbb{P}^2(K)$  to

$$E : Y^2Z = X^3 + aXZ^2 + bZ^3$$

- So the affine points  $(x, y)$  from before become  $(x : y : 1) \sim (\lambda x : \lambda y : \lambda)$  and the point at infinity is the unique point with  $Z = 0$ , i.e.,  $(0 : 1 : 0) \sim (0 : \lambda : 0)$

# Projective space, cont.

- One practical benefit of working over  $\mathbb{P}^2$  is that the explicit formulas for computing  $\oplus$  become much faster, by avoiding field inversions
- Thus, the fundamental ECC operation  $k, P \mapsto [k]P$  becomes much faster...

$$(x', y') = [2](x, y)$$

$$\lambda \leftarrow (3x^2 + a)/(2y);$$

$$x' \leftarrow \lambda^2 - 2x;$$

$$y' \leftarrow -(\lambda(x' - x) + y);$$

$$1S + 2M + 1I$$

$$(X' : Y' : Z') = [2](X : Y : Z)$$

$$X' = 2XY((3X^2 + aZ^2)^2 - 8Y^2XZ)$$

$$Y' = (3X^2 + aZ^2)(12Y^2XZ - (3X^2 + aZ^2)^2) - 8Y^4Z^2$$

$$Z' = 8Y^3Z^3$$

$$5M + 6S$$

# Projective scalar multiplications

How to compute  $k, Q \mapsto [k]Q$  on  $y^2 = x^3 + ax + b$ ?

$$k = (k_n, k_{n-1}, \dots, k_0)$$

$$(X_P : Y_P : Z_P) \leftarrow Q$$

for  $i$  from  $n - 1$  downto 0 do

$$(X_P : Y_P : Z_P) \leftarrow [2](X_P : Y_P : Z_P) \quad 5M + 6S$$

if  $k_i = 1$  then

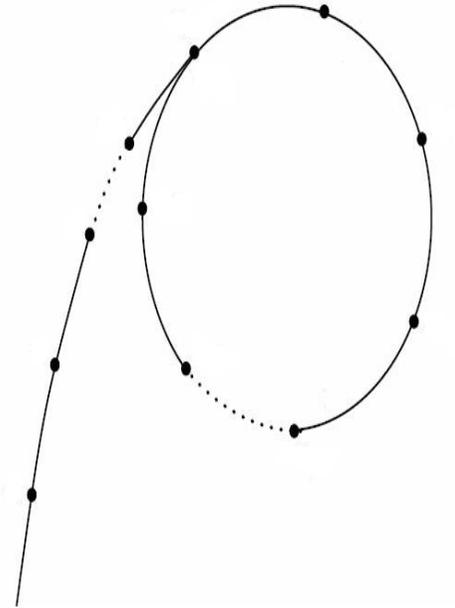

$$(X_P : Y_P : Z_P) \leftarrow (X_P : Y_P : Z_P) \oplus (X_Q : Y_Q : Z_Q) \quad 9M + 2S$$

end for

$$\text{return } (x_P, y_P) \leftarrow (X_P/Z_P, Y_P/Z_P) \quad 1I + 2M$$

# ECDLP security and Pollard's rho algorithm

- ECDLP: given  $P, Q \in E(\mathbb{F}_p)$  of prime order  $N$ , find  $k$  such that  $Q = [k]P$
- Pollard'78: compute pseudo-random  $R_i = [a_i]P + [b_i]Q$  until we find a collision  $R_i = R_j$  with  $b_i \neq b_j$ , then  $k = (a_j - a_i)/(b_i - b_j)$
- Birthday paradox says we can expect collision after computing  $\sqrt{\pi n/2}$  group elements  $R_i$ , i.e., after  $\approx \sqrt{N}$  group operations. So  $2^{128}$  security needs  $N \approx 2^{256}$
- The best known ECDLP algorithm on (well-chosen) elliptic curves remains generic, i.e., elliptic curves are as strong as is possible

# Index calculus on elliptic curves?

[Miller, 85] : "it is extremely unlikely that an index calculus [...] will ever be able to work"

Consider  $E/\mathbb{F}_{1217}$ :  $y^2 = x^3 - 3x + 139$

$$\#E(\mathbb{F}_{1217}) = 1277$$

$$P = (3,401) \text{ and } Q = (192,847)$$

ECDLP: find  $k$  such that  $[k]P = Q$

Regardless of factor base, can't efficiently decompose elements!

e.g., factor base  $R_i = \{(3,401), (5,395), (7,73), (11,252), (13,104), (19,265)\}$

Writing  $S = \sum [k_i]R_i$  involves solving discrete logarithms, compare this to integers **mod**  $p$  where we lift and factorise over the integers

Part 1: Motivation

Part 2: Elliptic Curves

Part 3: Elliptic Curve Cryptography

Part 4: Next-generation ECC

# What's wrong with old school ECC?

- **Side-channel attacks:** starting with Kocher'99, side-channel attacks and their countermeasures have become extremely sophisticated
- **Decades of new research:** we now know much better/faster/simpler/safer ways to do ECC
- **Suspicion surrounding previous standards:** Snowden leaks, dual EC-DRBG backdoor, etc., lead to conjectured weaknesses in the NIST curves

# Next generation elliptic curves

- 2014: CFRG receives formal request from TLS working group for recommendations for new elliptic curves
- 2015: NIST holds workshop on ECC standards
- 2015: CFRG announces two chosen curves, both specified in Montgomery (1987) form

$$E/\mathbb{F}_p : y^2 = x^3 + Ax^2 + x$$

- Bernstein's Curve25519 [2006]:  $p = 2^{255} - 19$  and  $A = 486662$
- Hamburg's Goldilocks [2015]:  $p = 2^{448} - 2^{224} - 1$  and  $A = 156326$
- Both primes offer fast software implementations!
- Their group orders are divisible by 8 and 4, but this form offers several advantages.

# Montgomery's fast differential arithmetic

$$E/\mathbb{F}_p : y^2 = x^3 + Ax^2 + x$$

- drop the  $y$ -coordinate, and work with  $x$ -only.
- projectively, work with  $(X : Z) \in \mathbb{P}^1$  instead of  $(X : Y : Z) \in \mathbb{P}^2$
- But (pseudo-)addition of  $\mathbf{x}(P)$  and  $\mathbf{x}(Q)$  requires  $\mathbf{x}(Q \ominus P)$

Extremely fast pseudo-doubling: **xDBL**

$$X_{[2]P} = (X_P + Z_P)^2 (X_P - Z_P)^2$$

$$2M + 2S$$

$$Z_{[2]P} = 4X_P Z_P ((X_P - Z_P)^2 + (A + 2)X_P Z_P)$$

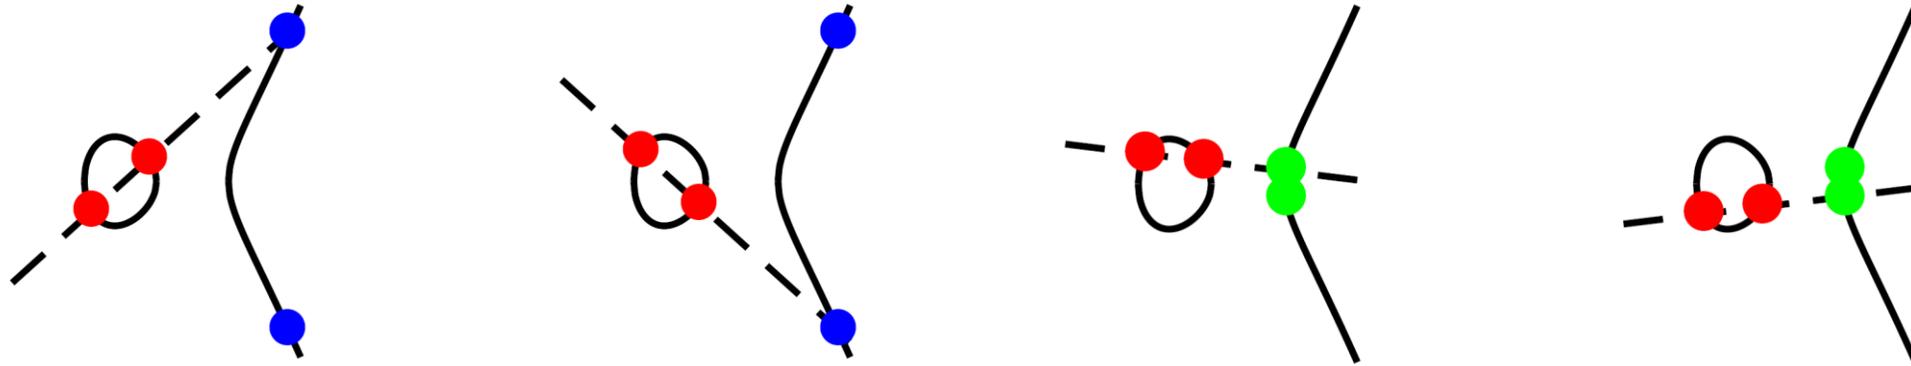

Extremely fast pseudo-addition: **xADD**

$$X_{P+Q} = Z_{P-Q} \left[ (X_P - Z_P)(X_Q + Z_Q) + (X_P + Z_P)(X_Q - Z_Q) \right]^2$$

$$4M + 2S$$

$$Z_{P+Q} = X_{P-Q} \left[ (X_P - Z_P)(X_Q + Z_Q) - (X_P + Z_P)(X_Q - Z_Q) \right]^2$$

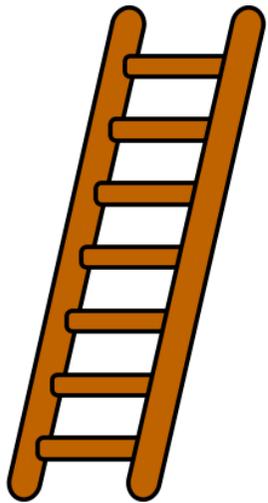

# Differential additions and the Montgomery ladder

- Given only the  $x$ -coordinates of two points, the  $x$ -coordinate of their sum can be two possibilities
- Inputting the  $x$ -coordinate of the *difference* resolves ambiguity
- The (ingenious!) Montgomery ladder fixes all *differences* as the input point: in  $k, x(P) \mapsto x([k]P)$ , every **xADD** is of the form
$$\mathbf{xADD}(x([n+1]P), x([n]P), x(P))$$
- We carry two multiples of  $P$  "up the ladder":  $x(Q)$  and  $x(Q \oplus P)$
- At  $i^{th}$  step: compute  $x([2]Q \oplus P) = \mathbf{xADD}(x(Q \oplus P), x(Q), x(P))$
- At  $i^{th}$  step: pseudo-double (**xDBL**) one of them depending on  $k_i$

# Fast, compact, simple, safer Diffie-Hellman

- Write  $k = \sum_{i=0}^{\ell-1} k_i 2^i$  with  $k_{\ell-1} = 1$  and  $P = (x_P, y_P)$  in  $E[n]$  (e.g., on Curve25519 or Goldilocks)

```
(x0, x1) ← (xDBL(xP), xP)
for i = ℓ - 2 downto 0 do
  (x0, x1) ← cSWAP((ki+1 ⊗ ki), (x0, x1))
  (x0, x1) ← (xDBL(x0), xADD(x0, x1, xP))
end for
(x0, x1) ← cSWAP(k0, (x0, x1))
return x0 (= x[k]P)
```

Inherently uniform, much easier to implement in constant-time

- $x$ -only Diffie-Hellman (Miller'85):  $x([ab]P) = x([a]([b]P)) = x([b]([a]P))$

see <https://tools.ietf.org/html/rfc7748>

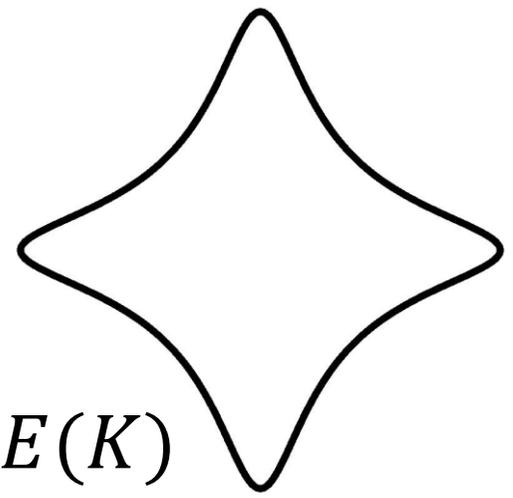

(Elliptic curves for security)

# Curve25519 and Goldilocks in the real world

- See “Elliptic curves for security” <https://tools.ietf.org/html/rfc7748>
- Both curves integrated into TLS ciphersuites
- In 2014, OpenSSH defaults to Curve25519
- Curve25519 is used in Signal Protocol (Facebook Messenger, Google Allo, WhatsApp), iOS, GnuPG, etc (<https://en.wikipedia.org/wiki/Curve25519>)

# (Twisted) Edwards curves

$$E : ax^2 + y^2 = 1 + dx^2y^2$$

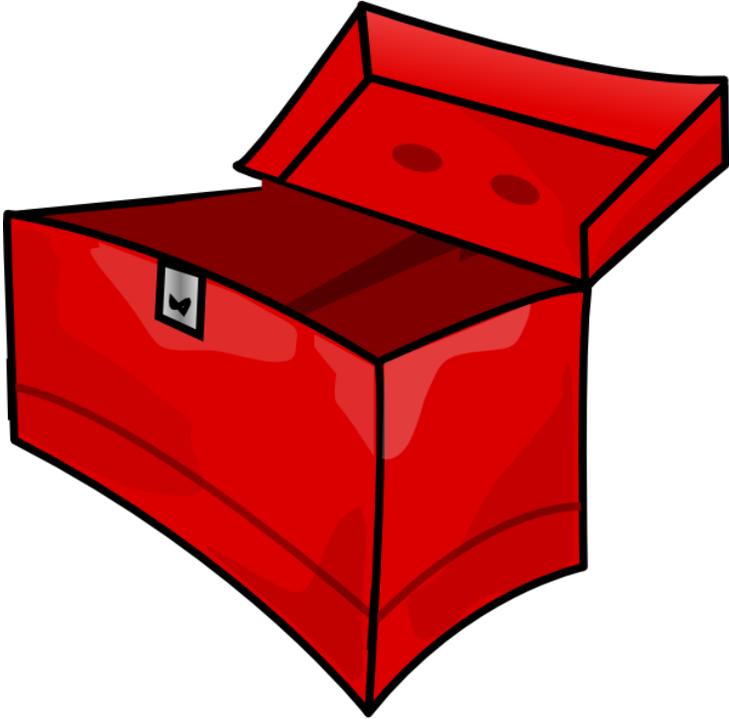

- Neutral element is  $(0,1)$  - no projective space needed for  $E(K)$
- Addition law is *complete* (for well-chosen  $E$ )

$$(x_1, y_1) + (x_2, y_2) = \left( \frac{x_1y_1 + x_2y_2}{y_1y_2 - x_1x_2}, \frac{x_1y_1 - x_2y_2}{x_1y_2 - y_1x_2} \right)$$

- Extremely fast: **8M!** Also works for doubling, inverses, everything
- Fast, simple, exception-free implementations that always compute correctly
- Also birationally equivalent to Montgomery curves!

ECC is the best of both worlds

attacker's toolbox

vs.

our toolbox
